Humanosphere Potentiality Index

Many of the so-called developed countries have narrowly set production and increased productivity as societal goals. Under this production-centric worldview, per capita GDP (or GNP) has long been a de facto indicator of the wealth of citizens even though numerous problems have been pointed out. Since the beginning of the 1990s, various organizations have become engaged in efforts to develop indices to take the place of GDP and to evaluate the state of the world from the standpoint of new concepts such as ‘sustainability’ or ‘human development’. However, no index has been developed that attempts to place human activities within the context of global atmospheric-hydrological circulation or the capacities of the world’s diverse life forms.

RESPONDING TO THE CURRENT TREND of developing indices and concerned with how to read the state of the world, we have developed a Humanosphere Potentiality Index (HPI), with the aim of addressing the present and future welfare of human societies within a broader context of environmental sustainability. This perspective is derived from the concept of the ‘humanosphere’, as explained in the introduction of this focus issue, and expresses our dissatisfaction with the limits of measuring the status of human societies through the Human Development Index (HDI).

**Humanosphere: an analytical framework to assess humanosphere potentiality**

The humanosphere is chronologically made up of three spheres: the geosphere, biosphere and human society. These three spheres have historically interacted with each other and inform our current place in the world, and possess their own inherent logics. The geosphere in terms of ‘circulation’, the biosphere in terms of ‘diversity’ and human societies in terms of ‘autonomy and empathy’ (fig. 1). In working towards a sustainable humanosphere, we believe it is important for human societies to acknowledge two fundamental points: that human societies have developed through their interactions with both the geosphere and biosphere; and that there is a need to reconstruct our relationships with them by understanding how their logics influence the sustainable development of human societies.

Our strategic intention has been to offer an alternative to HDI. In 1990, the UNDP announced HDI with the intention to offer an alternative to GDP (GNP). The index was founded on a theory known as the capability approach – what individuals are capable of – advocated by the economist Amartya K. Sen. HDI is the outcome of a calculation that involves simply averaging three functions of human development: capabilities in health, education and income. We offer a different viewpoint to HDI. HPI is neither a simple attempt to reverse the view of the world as seen through HDI, nor is it merely an ‘additional perspective’. Rather, HPI attempts to evaluate the potentiality of the geosphere, biosphere and human societies to support our livelihood through a clearly defined logical framework. As a result, we are expanding the viewpoint of HDI.

If we consider HDI from the perspective of HPI we see that its focus is on an evaluation of the ‘autonomic’ achievement of better livelihood. HDI is also founded on the idea that it is crucial for individuals to be able to gain access to fundamental services (health, education and income) and collectively create and pursue value in their own lives. The HPI extends the perspective of evaluation to include the potential for sustainable development. This approach was adopted to consider care practices of human societies and their fundamental ability to empathize. Ultimately, it makes an evaluation which acknowledges the core logics of circulation in the geosphere and diversity in the biosphere. As we will show, through considering HDI from this expanded perspective and based on the layered logics, unexpected correlations and differing viewpoints become apparent.

**Calculating the Humanosphere Potentiality Index (HPI)**

Through a research project that has run for over five years, a team of researchers working in Asia and Africa created the components of HPI (fig. 2). We created nine indices that are expressed as a three by three index to include potentiality, availability indicators, and disturbance indicators in each sphere. Our potentiality indicator refers to the quantitative scale that each sphere possesses, while the availability indicator attempts to present the ‘proper’ relationships of the elements that compose each sphere. These two indicators are expressed using the value per unit of land area. The disturbance indicator presents human-induced negative effects that arise in the two spheres. We subtract this to adjust the potentiality of each sphere, keeping modern human society in mind. As such, the disturbance indicators are expressed using value per capita, and not value per unit of land area.

To represent the geosphere, we chose three indicators: solar energy, an atmospheric-hydrological circulation index (as a potentiality and availability indicator), and CO2 emissions to express the logic of circulation, which all have established accessible databases. Likewise, for the biosphere biomass, the biodiversity index and human appropriated net primary production (HANPP) were included to express relations. Biomass is represented by forest biomass per unit area because forests account for almost 90% of the total plant biomass in the world. The biodiversity index estimates the biodiversity of terrestrial ecosystems based on the numbers of species of vascular plants, amphibians, reptiles, birds and mammals. HANPP as a disturbance indicator explains the per capita appropriation of the net primary production of human activities.

To create an index for human society, we adopted population, care relations and total unexpected deaths. These indicators reflect the idea that there are two fundamental logics that characterize human society, namely autonomy and empathy that form a basis to make possible care relations. We chose population as a potentiality indicator as all human societies show tolerance and consideration towards each other. As such, population sizes represent the potential magnitudes of care relations. We have calculated care relations through two elements: the first one is the sharing of abodes, which expresses potential care access in the household, and the female-to-male ratio, which expresses fundamental gender equality in household care relations. Total unexpected deaths are the sum of the number of deaths resulting from the actions of the geosphere (disasters), biosphere (infectious disease), and human society (intentional injuries). In each sphere, the three figures that express potentiality, availability and disturbance are integrated into a composite index, creating a simple average of three indicators. The HPI is an integrated index averaging these three indices.

**Humanosphere Potentiality Index (HPI) and the Human Development Index (HDI)**

Figure 3 is a representation of the world from the perspective of HPI. Those countries that have a higher HPI value possess a higher potentiality of sustainable development than countries with lower scores. It shows that the indices for the tropical zones of South East Asia and Latin America are as high as those of South Asia, Central Africa and parts of the Middle East. In the countries with the highest HPI figures, the human society index is above average, in addition to the fact that the...
indicates the sustainability of geosphere, biosphere and human society.

There is a synchronizing elevated tendency between HPI and HDI in tropical zones but, its disappearance in temperate ones is an interesting finding. Nonetheless, we see a clearly observed correlation in countries between HDI and CO2 emissions in both tropical and temperate zones. Fundamentally, this means that the countries that have achieved a high HDI on HPI have been contributing to the deterioration of the environment regardless of where the country is located.

In search of a sustainable humanosphere

The aim of our work has been to construct and propose the establishment of HPI through the critical incorporation of existing indices such as HDI and others. The most central characteristic of HPI is that it offers a positive evaluation of tropical zones, such as Southeast Asia, where some of the world’s richest ecosystems lie. By comparing HDI and HPI, it becomes clear that the evaluation reached for tropical zones stands out in stark contrast. This is derived from a difference of perspective in respective evaluations. HDI evaluates three dimensions that include health, education and income, with a focus on an ‘autonomous’ achievement of ‘better’ livelihood (i.e., human development) – while HPI focuses on values for livelihood that incorporate circulation and diversity, autonomy and empathy. With increased material prosperity, we tend to think that countries in the temperate zones, including Western nations and Japan, lead a life of abundance whereas the tropical countries located in South East Asia and Africa, exist in poverty. However, such an ingrained belief can be questioned by asking in what sense do we really have ‘satisfying’ lives? Will such lives ensure our livelihoods with sustainability? Our HPI casts this into question.

Our index provides only a snapshot of how things have progressed so far. We cannot predict any trend in the decrease of forested areas and we cannot propose or evaluate ideal technologies or specific structures for institutions in different regions to deal with changes. As such, HDPI’s limitations in that ultimately, it is a crude index. However, what it enables us to do is to provide an indication of the world’s current situation in a much more comprehensive manner by presenting an agenda that is neither included nor addressed by HDI.

The HPI underlines the crucial message that we must pay much more attention not only to development but also to our ‘potentiality’ from the perspective of the humanosphere, in order to promote a sustainable livelihood for all human societies. Ultimately, the world viewed through an index such as HPI can make us rethink human development from within a much broader and deeper context, that of the ‘sustainable humanosphere.’
